Splitting-Connectivity bounds

The central problem of Statistical Learning

$X = \{x_1, \ldots, x_\ell\}$ — a finite training set of objects,
A — a set of classifiers,

$a = \arg\min\limits_{a \in A} Err(a, X)$ — the empirical risk minimization,
or, more commonly,

$a = \mu(X)$ — a *learning algorithm* μ trains a classifier a on a set X.

The Generalization Problem:

1. How to bound a testing error $Err(a, \bar{X})$, where
   $\bar{X} = \{x'_1, \ldots, x'_k\}$ is an independent testing set?
2. How to design learning algorithms that generalize well,
   i.e. have a small testing error $Err(a, \bar{X})$ almost always?

Combinatorial framework for generalization bounds

Applications to learning algorithms design

Overfitting
Links to Cross-Validation and Rademacher Complexity
Splitting-Connectivity bounds

The classical approach to Generalization Bounds

In classical approach one find the uniform convergence conditions:

$$\mathsf{P}_{\bar{X}} \Big(\sup_{a \in A} \big| P(a) - Err(a, X) \big| \geqslant \varepsilon \Big) \leqslant \mathsf{GenBound}(\ell, k, A, \varepsilon)$$

where $P(a) = \mathsf{E}_{\bar{X}} Err(a, \bar{X})$.

The Problem:

- GenBound may be very loose: $\sim 10^5 .. 10^{11}$ in realistic cases

To tackle the problem we

1. modify the functional at the left-side of the inequality
2. propose a combinatorial approach to get the bound

Combinatorial framework for generalization bounds

Applications to learning algorithms design

Overfitting
Links to Cross-Validation and Rademacher Complexity
Splitting-Connectivity bounds

The classical vs. combinatorial approach (#1 from 4)

In classical approach one find the uniform convergence conditions:

$$\mathsf{P}_X \Big(\sup_{a \in A} \big| P(a) - Err(a, X) \big| \geqslant \varepsilon \Big) \leqslant \mathsf{GenBound}(\ell, k, A, \varepsilon)$$

In combinatorial approach instead of a probability of error $P(a)$ we bound a testing error:

$$\mathsf{P}_{X, \bar{X}} \Big(\sup_{a \in A} \big| Err(a, \bar{X}) - Err(a, X) \big| \geqslant \varepsilon \Big) \leqslant \mathsf{GenBound}(\ell, k, A, \varepsilon)$$

Motivation:

- we bound an empirically measurable quantity of *overfitting*:

$$\delta(a, X, \bar{X}) = Err(a, \bar{X}) - Err(a, X)$$

- we remove a redundant technical step of *symmetrization* that weakens the bound without adding a sense to the result

Combinatorial framework for generalization bounds
Combinatorial theory of overfitting: overview
Applications to learning algorithms design

Overfitting
Links to Cross-Validation and Rademacher Complexity
Splitting-Connectivity bounds

The classical vs. combinatorial approach (#2 from 4)

In classical approach one find the uniform convergence conditions:

$$\mathsf{P}_X\Big(\sup_{a\in A}\big|P(a) - Err(a, X)\big| \geqslant \varepsilon\Big) \leqslant \mathsf{GenBound}(\ell, k, A, \varepsilon)$$

In combinatorial approach instead of supremum over A
we use a learning algorithm μ:

$$\mathsf{P}_{X,\bar{X}}\Big(\big|Err(\mu(X), \bar{X}) - Err(\mu(X), X)\big| \geqslant \varepsilon\Big) \leqslant \mathsf{GenBound}(\ell, k, \mu, \varepsilon)$$

Motivation:

- we discard bad classifiers that do not work in a learning task
- we take into account the learning algorithm μ

Combinatorial framework for generalization bounds
Combinatorial theory of overfitting: overview
Applications to learning algorithms design

Overfitting
Links to Cross-Validation and Rademacher Complexity
Splitting-Connectivity bounds

The classical vs. combinatorial approach (#3 from 4)

In classical approach one find the uniform convergence conditions:
$$\mathsf{P}_X \Big(\sup_{a \in A} \big| P(a) - Err(a, X) \big| \geqslant \varepsilon \Big) \leqslant \mathsf{GenBound}(\ell, k, A, \varepsilon)$$

In combinatorial approach instead of usual i.i.d. assumption
we use a uniform distribution over all partitions $\mathbb{X}^L = X \sqcup \bar{X}$:
$$\frac{1}{C_L^\ell} \sum_{\substack{X \subset \mathbb{X}^L \\ |X| = \ell}} \Big[\big| Err(\mu(X), \bar{X}) - Err(\mu(X), X) \big| \geqslant \varepsilon \Big] \leqslant \mathsf{GenBound}(\mathbb{X}^L, \mu, \varepsilon)$$

Motivation:

- we make a left-side part of the inequality empirically measurable
- we make a bound data-dependent
- we remove a redundant step of integration over object space

Combinatorial framework for generalization bounds
Combinatorial theory of overfitting: overview
Applications to learning algorithms design

Overfitting
Links to Cross-Validation and Rademacher Complexity
Splitting-Connectivity bounds

The classical vs. combinatorial approach (#4 from 4)

In classical approach one find the uniform convergence conditions:
$$\mathsf{P}_X\Big(\sup_{a \in A} \big|P(a) - Err(a, X)\big| \geqslant \varepsilon \Big) \leqslant \mathsf{GenBound}(\ell, k, A, \varepsilon)$$

In combinatorial approach instead of two-side deviation
we remove $|\cdot|$ and estimate one-side deviation:
$$\mathsf{P}_{X \sim \mathbb{X}^L}\Big[Err(\mu(X), \bar{X}) - Err(\mu(X), X) \geqslant \varepsilon \Big] \leqslant \mathsf{GenBound}(\mathbb{X}^L, \mu, \varepsilon)$$

Motivation:

- we discard a non-interesting case of negative overfitting

Splitting-Connectivity bounds

Learning with binary loss

$\mathbb{X}^L = \{x_1, \dots, x_L\}$ — a finite universe set of objects

$A = \{a_1, \dots, a_D\}$ — a finite set of classifiers

$I(a, x) = [\text{classifier } a \text{ makes an error on object } x]$ — binary loss
Error matrix of size $L \times D$, all columns are distinct:

	a_1	a_2	a_3	a_4	a_5	a_6	$\cdots$	a_D	
x_1	1	1	0	0	0	1	$\cdots$	1	X — observable
$\dots$	0	0	0	0	1	1	$\cdots$	1	training sample
x_ℓ	0	0	1	0	0	0	$\cdots$	0	of size ℓ
$x_{\ell+1}$	0	0	0	1	1	1	$\cdots$	0	$\bar{X}$ — hidden
$\dots$	0	0	0	1	0	0	$\cdots$	1	testing sample
x_L	0	1	1	1	1	1	$\cdots$	0	od size $k = L - \ell$

$a \mapsto \big(I(a, x_i)\big)_{i=1}^{L}$ — binary *error vector* of classifier a

$\nu(a, X) = \frac{1}{|X|} \sum\limits_{x \in X} I(a, x)$ — *error rate* of a on a sample $X \subset \mathbb{X}^L$

Probability of large overfitting

$\mu\colon X \mapsto a$ — *learning algorithm*
$\nu(\mu X, X)$ — *training error rate*
$\nu(\mu X, \bar{X})$ — *testing error rate*
$\delta(\mu, X) \equiv \nu(\mu X, \bar{X}) - \nu(\mu X, X)$ — *overfitting* of μ on X and $\bar{X}$

Axiom (weaken i.i.d. assumption)

$\mathbb{X}^L$ *is not random, all partitions* $\mathbb{X}^L = X \sqcup \bar{X}$ *are equiprobable,*
    X — *observable training sample of a fixed size* ℓ,
    $\bar{X}$ — *hidden testing sample of a fixed size* k, $L = \ell + k$

Def. *Probability of large overfitting*

$$Q_\varepsilon(\mu, \mathbb{X}^L) = \mathsf{P}\big[\delta(\mu, X) \geqslant \varepsilon\big] = \frac{1}{C_L^\ell} \sum_{X \subset \mathbb{X}^L} \big[\delta(\mu, X) \geqslant \varepsilon\big]$$

Splitting-Connectivity bounds

Bounding problems

- Probability of large overfitting:

$$Q_\varepsilon(\mu, \mathbb{X}^L) = \mathsf{P}\big[\delta(\mu, X) \geqslant \varepsilon\big] \leqslant?$$

- Probability of large testing error:

$$R_\varepsilon(\mu, \mathbb{X}^L) = \mathsf{P}\big[\nu(\mu X, \bar{X}) \geqslant \varepsilon\big] \leqslant?$$

- Expectation of OverFitting:

$$\mathsf{EOF}(\mu, \mathbb{X}^L) = \mathsf{E}\,\delta(\mu, X) \leqslant?$$

- Expectation of testing error (Complete Cross-Validation):

$$\mathsf{CCV}(\mu, \mathbb{X}^L) = \mathsf{E}\,\nu\big(\mu X, \bar{X}\big) \leqslant?$$

Combinatorial framework for generalization bounds
Combinatorial theory of overfitting: overview
Applications to learning algorithms design

Overfitting
Links to Cross-Validation and Rademacher Complexity
Splitting-Connectivity bounds

Links to Cross-Validation

Taking expectation is equivalent to averaging over all partitions.
Expected testing error also called Complete Cross-Validation:

$$\mathsf{CCV}(\mu, \mathbb{X}^L) = \frac{1}{|X|} \sum_{x \in X} \nu(\mu X, \bar{X})$$

Usual cross-validation techniques (e.g. hold-out, t-fold, $q \times t$-fold, partition sampling, etc.) can be viewed as empirical measurement of CCV by averaging over a representative subset of partitions.

Leave-One-Out is equivalent to CCV for the case $k = 1$.

:) Combinatorial functionals Q_ε, R_ε, CCV, EOF can be easily measured empirically by generating $\sim 10^3$ random partitions.

Combinatorial framework for generalization bounds
Combinatorial theory of overfitting: overview
Applications to learning algorithms design

Overfitting
Links to Cross-Validation and Rademacher Complexity
Splitting-Connectivity bounds

Links to Local Rademacher Complexity

Def. *Local Rademacher complexity* of the set A on $\mathbb{X}^L$

$$\mathcal{R}(A, \mathbb{X}^L) = \mathsf{E}_\sigma \sup_{a \in A} \frac{2}{L} \sum_{i=1}^{L} \sigma_i I(a, x_i), \qquad \sigma_i = \begin{cases} +1, & \text{prob. } \frac{1}{2} \\ -1, & \text{prob. } \frac{1}{2} \end{cases}$$

$\sigma_1, \ldots, \sigma_L$ — independent Rademacher random variables.

Expected overfitting is almost the same thing for the case $\ell = k$:

$$\mathsf{EOF}(\mu, \mathbb{X}^L) = \mathsf{E} \sup_{a \in A} \frac{2}{L} \sum_{i=1}^{L} \sigma_i I(a, x_i), \qquad \sigma_i = \begin{cases} +1, & x_i \in \bar{X} \\ -1, & x_i \in X \end{cases}$$

where μ is *overfitting maximization* (very unnatural learning!):

$$\mu X = \arg \max_{a \in A} \Big(\nu(a, \bar{X}) - \nu(a, X) \Big)$$

Combinatorial framework for generalization bounds
Combinatorial theory of overfitting: overview
Applications to learning algorithms design

Overfitting
Links to Cross-Validation and Rademacher Complexity
Splitting-Connectivity bounds

Links to usual SLT framework

Usual probabilistic assumptions:
$\mathbb{X}^L$ is i.i.d. from probability space $\langle \mathscr{X}, \sigma, \mathsf{P} \rangle$ on infinite $\mathscr{X}$

Transferring of combinatorial generalization bound to i.i.d.
framework first used in (Vapnik and Chervonenkis, 1971):

1 Give a combinatorial bound on probability of large overfitting:

$$\mathsf{P}_{X \sim \mathbb{X}^L} \big[\delta(\mu, X) \geqslant \varepsilon \big] = Q_\varepsilon(\mu, \mathbb{X}^L) \leqslant \eta(\varepsilon, \mathbb{X}^L)$$

2 Take expectation on $\mathbb{X}^L$:

$$\mathsf{P}_{X \sim \mathscr{X}^\ell, \bar{X} \sim \mathscr{X}^k} \big[\delta(\mu, X) \geqslant \varepsilon \big] =$$
$$= \mathsf{E}_{\mathbb{X}^L} \, Q_\varepsilon(\mu, \mathbb{X}^L) \leqslant \mathsf{E}_{\mathbb{X}^L} \, \eta(\varepsilon, \mathbb{X}^L).$$

Overfitting
Links to Cross-Validation and Rademacher Complexity
Splitting-Connectivity bounds

Splitting-Connectivity graph (1-inclusion graph)

Define two binary relations on classifiers:

partial order $a \leqslant b$: $I(a, x) \leqslant I(b, x)$ for all $x \in \mathbb{X}^L$;

precedence $a \prec b$: $a \leqslant b$ and Hamming distance $\|b - a\| = 1$.

Definition (SC-graph)

*Splitting and Connectivity (SC-) graph $\langle A, E \rangle$:*

A — *a set of classifiers with distinct binary error vectors;*

$E = \big\{(a, b) \colon a \prec b\big\}$.
Properties of the SC-graph:

- each edge (a, b) is labeled by an object $x_{ab} \in \mathbb{X}^L$ such that
  $0 = I(a, x_{ab}) < I(b, x_{ab}) = 1$;

- multipartite graph with layers
  $A_m = \big\{a \in A \colon \nu(a, \mathbb{X}^L) = \frac{m}{L}\big\}, \;\; m = 0, \ldots, L+1$;

Splitting-Connectivity bounds

Connectivity and inferiority of a classifier

Def. *Connectivity* of a classifier $a \in A$:
$u(a) = \#\{x_{ab} \in \mathbb{X}^L \colon a \prec b\}$ — up-connectivity,
$d(a) = \#\{x_{ba} \in \mathbb{X}^L \colon b \prec a\}$ — down-connectivity.

Def. *Inferiority* of a classifier $a \in A$
$q(a) = \#\{x_{cb} \in \mathbb{X}^L \colon \exists b \;\; c \prec b \leqslant a\}$
Inferiority:
$d(a) \leqslant q(a) \leqslant L\nu(a, \mathbb{X}^L)$

Example:
$u(a) = \#\{x3, x4\} = 2$
$d(a) = \#\{x1, x2\} = 2$
$q(a) = \#\{x1, x2\} = 2$

Splitting-Connectivity bounds

The Splitting–Connectivity (SC-) bound

Empirical Risk Minimization (ERM) — learning algorithm μ:

$$\mu X \in A(X), \qquad A(X) = \operatorname{Arg\,min}_{a \in A} \nu(a, X)$$

Theorem (SC-bound)

For any $\mathbb{X}^L$, A, ERM μ, and $\varepsilon \in (0, 1)$

$$Q_\varepsilon \leqslant \sum_{a \in A} \frac{C_{L-u-q}^{\ell-u}}{C_L^\ell} H_{L-u-q}^{\ell-u,\, m-q}(\varepsilon),$$

where $m = L\nu(a, \mathbb{X}^L)$, $u = u(a)$, $q = q(a)$,

$$H_L^{\ell,\, m}(\varepsilon) = \sum_{s=0}^{\lfloor (m-\varepsilon k)\ell/L \rfloor} \frac{C_m^s C_{L-m}^{\ell-s}}{C_L^\ell} - \text{hypergeometric tail function.}$$

Combinatorial framework for generalization bounds
Combinatorial theory of overfitting: overview
Applications to learning algorithms design

Overfitting
Links to Cross-Validation and Rademacher Complexity
Splitting-Connectivity bounds

The properties of the SC-bound

$$Q_\varepsilon \leqslant \sum_{a \in A} \frac{C_{L-u-q}^{\ell-u}}{C_L^\ell} H_{L-u-q}^{\ell-u,\,m-q}(\varepsilon)$$

1. If $|A| = 1$ then SC-bound gives an exact estimate of testing error for a single classifier:

$$Q_\varepsilon = \mathsf{P}\big[\nu(a, \bar{X}) - \nu(a, X) > \varepsilon\big] = H_L^{\ell,\,m}(\varepsilon) \overset{\ell=k}{\leqslant} \tfrac{3}{2} e^{-\varepsilon^2 \ell}$$

2. Substitution $u(a) \equiv q(a) \equiv 0$ transforms the SC-bound into Vapnik–Chervonenkis bound:

$$Q_\varepsilon \leqslant \sum_{a \in A} H_L^{\ell,\,m}(\varepsilon) \overset{\ell=k}{\leqslant} |A| \cdot \tfrac{3}{2} e^{-\varepsilon^2 \ell}$$

Combinatorial framework for generalization bounds
Combinatorial theory of overfitting: overview
Applications to learning algorithms design

Overfitting
Links to Cross-Validation and Rademacher Complexity
Splitting-Connectivity bounds

The properties of the SC-bound

$$Q_\varepsilon \leqslant \sum_{a \in A} \frac{C_{L-u-q}^{\ell-u}}{C_L^\ell} H_{L-u-q}^{\ell-u,\, m-q}(\varepsilon)$$

④ The probability to get a classifier a as a result of learning:

$$\mathsf{P}[\mu X = a] \leqslant \frac{C_{L-u-q}^{\ell-u}}{C_L^\ell}$$

⑤ The contribution of $a \in A$ decreases exponentially by:
$u(a) \Rightarrow$ **connected sets are less subjected to overfitting**;
$q(a) \Rightarrow$ **only lower layers contribute significantly to Q_ε.**

⑥ The SC-bound is *exact* for some nontrivial sets of classifiers.

Sets of classifiers with known combinatorial bounds

Model sets of classifiers with **exact** SC-bound:

- monotone and unimodal *n*-dimensional lattices (Botov, 2010)
- pencils of monotone chains (Frey, 2011)
- intervals in boolean cube and their slices (Vorontsov, 2009)
- Hamming balls in boolean cube and their slices (Frey, 2010)
- sparse subsets of lattices and Hamming balls (Frey, 2011)

Real sets of classifiers with **tight** computable SC-bound:

- conjunction rules (Ivahnenko, 2010)
- linear classifiers (Sokolov, 2012)
- decision stumps or arbitrary chains (Ishkina, 2013)

**Real** sets of classifiers with **exact** computable not-SC bound:

- *k* nearest neighbor classification (Vorontsov, 2004; Ivanov, 2009)
- isotonic separation (Vorontsov and Makhina, 2011; Guz, 2011)

Combinatorial framework for generalization bounds

Applications to learning algorithms design

Model sets for which exact bounds are known
Bound computation via Random Walks
Making bounds observable

Some theoretical and practical results for model sets

1. Necessary and sufficient conditions for the SC-bound exactness:
   1) a graph must have unique source and unique sink
   2) for any $a \in A$ with n outgoing edges a set A must contain
   an n-dimensional cube induced by these edges
   (Zhivotovskiy, 2012)

2. Low-dimensional unimodal lattice can be used to approximate
   a set of rules in decision tree nodes.
   This helps to find less overfitted node splits
   (Botov, 2011)

3. Covering a set of classifiers A by slices of Hamming balls helps
   to obtain tighter generalization bound
   (Frey, 2013)

Special kind of Random Walks for multipartite graph:
1) based on Frontier sampling algorithm
2) do not permit to walk in higher layers of a graph
3) estimate contributions of layers separately
Simple random walk:

Random walk with gravitation:

Combinatorial framework for generalization bounds
Combinatorial theory of overfitting: overview
Applications to learning algorithms design

Model sets for which exact bounds are known
Bound computation via Random Walks
Making bounds observable

Making bounds observable

SCbound$(\mu, \mathbb{X}^L)$ depends on a hidden set $\bar{X}$, then we use
SCbound(μ, X) instead.
Open problems: is it correct? why? may be not always?

Really EOF(μ, X) is well concentrated near to EOF$(\mu, \mathbb{X}^L)$:
Experiments on model data, $L = 60$, testing sample size $K = 60$

Applications to learning algorithms design

Ensembles of Conjunction Rules
Ensembles of low-dimensional Linear Classifiers
Comparing with state-of-art PAC-Bayesian bounds

Ensemble learning

2-class classification problem:
$(x_i, y_i)_{i=1}^{L}$ — training set, $x_i \in \mathbb{R}^n$, $y_i \in \{-1, +1\}$

Ensemble — *weighted voting* of base weak classifiers $b_t(x)$:

$$a(x) = \operatorname{sign} \sum_{t=1}^{T} w_t b_t(x)$$

Main idea is to apply generalization bound
as features selection criterion in base classifiers

Our goals:
1) to reduce overfitting of base classifiers
2) to reduce the complexity of composition T

ComBoost: Committee boosting

Instead of objects reweighting ComBoost trains each base classifier on the training subset $X' \subset X$ in order to augment margins of the ensemble as much as possible:

$$X' = \left\{ x_i \in X \colon M_0 \leqslant \mathsf{Margin}(i) \leqslant M_1 \right\}$$

$$\mathsf{Margin}(i) = y_i \sum_{t=1}^{T} w_t b_t(x_i).$$

Distribution of margins

Ensembles of low-dimensional Linear Classifiers
Comparing with state-of-art PAC-Bayesian bounds

Learning ensembles of Conjunction Rules

Conjunction rule is a simple well interpretable 1-class classifier:

$$r_y(x) = \bigwedge_{j \in J} \big[f_j(x) \lessgtr_j \theta_j \big],$$

where $f_j(x)$ — features
$J \subseteq \{1, \ldots, n\}$ — a small subset of features
θ_j — thresholds
$\lessgtr_j$ — one of the signs $\leqslant$ or $\geqslant$
y — the class of the rule

Weighted voting of rule sets R_y, $y \in Y$:

$$a(x) = \arg \max_{y \in Y} \sum_{r \in R_y} w_r r(x)$$

We use SC-bounds to reduce overfitting of rule learning

Combinatorial framework for generalization bounds
Combinatorial theory of overfitting: overview
Applications to learning algorithms design

Ensembles of Conjunction Rules
Ensembles of low-dimensional Linear Classifiers
Comparing with state-of-art PAC-Bayesian bounds

Classes of equivalent rules: one point per rule

Example: separable 2-dimensional task, $L = 10$, two classes.
rules: $r(x) = \big[f_1(x) \leqslant \theta_1\big] \wedge \big[f_2(x) \leqslant \theta_2\big]$.

Experiment 1: ComBoost ensemble of linear classifiers

	statlog	waveform	wine	faults
ERM + MCCV	**85,35**	87,56	**71,63**	**73,62**
ERM + SC-bound	**85,08**	**87,66**	71,08	**71,65**
LR + MCCV	84,04	**88,13**	**71,52**	70,86
LR	80,77	87,34	71,49	71,09
PacBayes DD	82,13	87,17	64,68	67,67

The percentage of correct predictions on testing set (averaged over 5 partitions). Two top results for every task are shown in **bold**.

Feature selection criteria:
- ERM — learning by minimizing error rate from subset of classifiers sampled from random walks
- LR — learning by Logistic Regression
- MCCV — Monte-Carlo cross-validation
- DD — PAC-Bayes Dimension-Dependent bound (Jin, 2012)

Combinatorial framework for generalization bounds
Combinatorial theory of overfitting: overview
Applications to learning algorithms design

Ensembles of Conjunction Rules
Ensembles of low-dimensional Linear Classifiers
Comparing with state-of-art PAC-Bayesian bounds

Experiment 2: comparing bounds for Logistic Regression

All bounds are calculated from subset generated by random walk

- MC — Monte-Carlo bound (very slow)
- SC — Splitting-Connectivity bound
- VC — Vapnik–Chervonenkis bound
- DD — Dimension-Dependent PAC-Bayes bound (Jin, 2012)

UCI Task	MC	SC	VC	PAC DD
glass	0.115	0.146	0.356	0.913
liver	0.095	0.533	0.595	1.159
ionosphere	0.083	0.149	0.238	1.259
wdbc	0.052	0.070	0.136	0.949
australian	0.043	0.244	0.277	0.798
pima	0.045	0.373	0.410	0.823

Conclusions:

1) combinatorial bounds are much tighter than PAC-Bayes bounds
2) SC-bound initially proved for ERM fit well for Logistic Regression

Combinatorial framework for generalization bounds
Combinatorial theory of overfitting: overview
Applications to learning algorithms design

Conclusions

Combinatorial framework

- gives tight (in some cases exact) generalization bounds
- that can be computed approximately from Random Walks
- bypass significantly state-of-art PAC-Bayesian bounds

Restrictions:

- binary loss
- computational costs
- low sample sizes, low dimensions

Further work:

- more effective approximations
- bigger sample sizes, bigger dimensions
- more applications
